WIND-TUNNEL INVESTIGATION OF THE EFFECT OF TAB BALANCE ON
TAB AND CONTROL-SURFACE CHARACTERISTICS

By Jack D. Brewer and M. J. Queijo

SUMMARY

An investigation was conducted to furnish data on the effect of tab balance on tab and control-surface characteristics. The airfoil tested had a modified NACA 65₁-012 contour with a plain flap having a chord equal to 25 percent of the wing chord and with a tab having a chord equal to 25 percent of the flap chord and having several nose shapes and overhang lengths.

The results of the investigation indicated that, in general, tab balance affected tab hinge-moment characteristics in much the same manner that flap balance affects flap hinge-moment characteristics. A moderate amount of tab balance did not seem to have any adverse effect on flap hinge-moment characteristics. Transition strips placed near the leading edge of an airfoil reduced the effectiveness of either plain or balanced tabs. Opening the tab gap reduced the tab effectiveness, but the reduction became less as the tab balance was increased.

Application (by an approximate method) of the results to two typical airplanes indicated that the addition of overhang balance to spring tabs was an effective means of reducing the control forces of spring-tab ailerons. Tabs with sealed internal balances were generally less effective in reducing aileron control forces than tabs with round-nose overhangs of the same balance length.

INTRODUCTION

Some means of balancing the excessive aerodynamic forces on the control surfaces have been found necessary in the designs of large airplanes and high-speed airplanes. Results of tests reported in references 1 to 3 show spring tabs to be one of the most effective means of obtaining aerodynamic balance. In some cases, however, the control forces become quite large even with a spring-tab arrangement. A spring-tab analysis presented by Gates of Great Britain indicates that a large part of the control forces for spring-tab ailerons may

result from tab hinge moments. Some data (references 4 and 5) are available on plain-tab hinge moments but little, on balanced-tab hinge moments. The present tests were conducted in the $2\frac{1}{2}$ - by 6-foot test section of the Langley stability tunnel to provide such tab data in order to investigate the practicability of using tab balance to reduce control forces. The effects of transition strips and tab gap on hinge-moment characteristics were also investigated.

SYMBOLS

c_l	airfoil section lift coefficient
c_{h_f}	flap (or aileron) section hinge-moment coefficient
c_{h_t}	tab section hinge-moment coefficient
P_{R_f}	resultant flap (or aileron) balance-pressure coefficient $(P_f \text{Lower} - P_f \text{Upper})$
P_{R_t}	resultant tab balance-pressure coefficient $(P_t \text{Lower} - P_t \text{Upper})$
P_f	pressure coefficient above or below flap (or aileron) seal
P_t	pressure coefficient above or below tab seal
c	chord of basic airfoil with flap and tab neutral, feet
c_f	flap (or aileron) chord from flap (or aileron) hinge line to trailing edge with tab neutral, feet
c_t	tab chord from tab hinge line to trailing edge, feet
c_{b_f}	flap (or aileron) balance chord, distance from hinge line to a point midway between points of attachment of flexible seal of sealed internal balance, feet
c_{b_t}	tab balance chord; distance from tab hinge line to leading edge of exposed overhang balance or to a point midway between points of attachment of flexible seal of sealed internal balance, feet
y_1	distance from plane of symmetry to inboard end of aileron, feet

- y_0 distance from plane of symmetry to outboard end of aileron,
feet
 δ_f flap (or aileron) deflection with respect to airfoil, degrees
 $\Delta\delta_f$ total deflection of right and left flaps (or ailerons), degrees
 δ_t tab deflection with respect to flap, degrees
 α angle of attack, degrees
 ϕ trailing-edge angle, degrees (See fig. 1.)
 F control force, pounds
 k_1 ratio between angular deflection of control (stick or wheel)
and aileron deflection with spring tab fixed
 k_2 ratio between angular deflection of control (stick or wheel)
and tab deflection with aileron fixed
 k_3 spring constant, ratio of control (stick or wheel) force to
spring-tab deflection when aileron is held fixed and
airspeed is zero, pounds per degree
 F_1, F_2 correlation factors defined on page 41 of reference 9
 V indicated airspeed, miles per hour

$$\Delta c_{ht} \frac{\partial}{\partial \alpha} = c_{ht} \frac{\partial}{\partial \alpha}_{Balanced \ tab} - c_{ht} \frac{\partial}{\partial \alpha}_{Plain \ tab}$$

$$\Delta c_{ht} \frac{\partial}{\partial \delta_t} = c_{ht} \frac{\partial}{\partial \delta_t}_{Balanced \ tab} - c_{ht} \frac{\partial}{\partial \delta_t}_{Plain \ tab}$$

$$c_l \frac{\partial}{\partial \alpha} = \left(\frac{\partial c_l}{\partial \alpha} \right)_{\delta_f, \delta_t}$$

$$c_l \frac{\partial}{\partial \delta_f} = \left(\frac{\partial c_l}{\partial \delta_f} \right)_{\alpha, \delta_t}$$

$$c_l \frac{\partial}{\partial \delta_t} = \left(\frac{\partial c_l}{\partial \delta_t} \right)_{\alpha, \delta_f}$$

$$c_{hf} \frac{\partial}{\partial \alpha} = \left(\frac{\partial c_{hf}}{\partial \alpha} \right)_{\delta_f, \delta_t}$$

$$c_{hf\delta_f} = \left(\frac{\partial c_{hf}}{\partial \delta_f} \right)_{\alpha, \delta_t}$$

$$c_{hf\delta_t} = \left(\frac{\partial c_{hf}}{\partial \delta_t} \right)_{\alpha, \delta_f}$$

$$c_{ht\alpha} = \left(\frac{\partial c_{ht}}{\partial \alpha} \right)_{\delta_t, \delta_f}$$

$$c_{ht\delta_f} = \left(\frac{\partial c_{ht}}{\partial \delta_f} \right)_{\alpha, \delta_t}$$

$$c_{ht\delta_t} = \left(\frac{\partial c_{ht}}{\partial \delta_t} \right)_{\alpha, \delta_f}$$

$$P_{Rf\alpha} = \left(\frac{\partial P_{Rf}}{\partial \alpha} \right)_{\delta_f, \delta_t}$$

$$P_{Rf\delta_f} = \left(\frac{\partial P_{Rf}}{\partial \delta_f} \right)_{\alpha, \delta_t}$$

$$P_{Rf\delta_t} = \left(\frac{\partial P_{Rf}}{\partial \delta_t} \right)_{\alpha, \delta_f}$$

$$P_{Rt\alpha} = \left(\frac{\partial P_{Rt}}{\partial \alpha} \right)_{\delta_t, \delta_f}$$

$$P_{Rt\delta_f} = \left(\frac{\partial P_{Rt}}{\partial \delta_f} \right)_{\alpha, \delta_t}$$

$$P_{Rt\delta_t} = \left(\frac{\partial P_{Rt}}{\partial \delta_t} \right)_{\alpha, \delta_f}$$

The subscripts outside the parentheses of the foregoing partial derivatives indicate factors held constant during measurement of the derivatives.

APPARATUS AND TESTS

The tests of the present investigation were conducted in the $2\frac{1}{2}$ - by 6-foot test section of the Langley stability tunnel. The model had an airfoil chord of 2 feet and spanned the throat of the tunnel. Photographs of the model in the tunnel are presented in figure 2. The part of the model forward of the 75-percent-chord station was made of laminated mahogany and had an NACA 65₁-012 contour, but from the 75-percent-chord station to the trailing edge the wing had flat sides forming a trailing-edge angle of 13.5°. The ordinates of the modified airfoil are given in table I.

The model had a plain flap constructed of laminated mahogany with a steel central web to which a steel tab was attached; the flap chord was 25 percent of the airfoil chord. The tab had a chord equal to 25 percent of the flap chord and was equipped with several brass nose pieces of various shapes and overhang lengths. The dimensions of the flap and tab are shown in figure 1. The ordinates of the tab nose shapes are given in table II.

The part of the model forward of the 75-percent-chord station was attached rigidly to disks that were mounted flush with the tunnel walls. Clearance gaps of approximately 1/16 inch were left between the disks and the ends of the control surfaces.

The lift on the model was measured with an integrating manometer; flap hinge moments were measured with a calibrated spring balance; tab hinge moments were measured by calibrated electric strain gages; and the pressure differences (resultant balance pressures) were measured by U-tube manometers.

All of the tests were made at a dynamic pressure of 155.5 pounds per square foot. The corresponding Reynolds number and Mach number are 4.59×10^6 and 0.34, respectively.

The greater part of the tests were made with transition strips attached to the upper and lower surfaces of the model. The transition strips were made by cementing No. 60 carborundum grains to Scotch cellulose tape in a strip $\frac{1}{4}$ inch wide. The tape was attached to the model so that the leading edges of the carborundum strips were at the 1.0-percent-chord station.

Tests were made with the tab gap sealed and open for the round tab nose shapes (gap = 0.004c). The tab gap was open for all other tests. The flap gap was sealed for all tests.

CORRECTIONS

Corrections applied to the test data for the effect of jet boundaries are based on the equations of reference 6. The methods of reference 6 were extended in order to obtain the corrections to flap hinge-moment coefficient and resultant balance-pressure coefficient. The equations used in making the corrections were:

$$c_l = 0.963c_l'$$

$$\alpha = \alpha' + 0.231c_l \quad (\delta_f=0^\circ, \delta_t=0^\circ)$$

$$c_{h_f} = c_{h_f}' + 0.0087c_l'$$

$$P_{R_f} = P_{R_f}' - 0.042c_l'$$

Primed values refer to the uncorrected value.

The corrections do not take into account the tunnel-wall boundary-layer effects or the effects of the gaps between the ends of the control surfaces and the end disks. The angle-of-attack correction does not take into account the small effect of lift resulting from tab and flap deflections. The corrections for c_{h_t} and for P_{R_t} were found to be very small and were neglected.

RESULTS AND DISCUSSION

Presentation of Data

The data are presented as plots of airfoil section lift coefficient, flap section hinge-moment coefficient, tab section hinge-moment coefficient, and the resultant flap balance-pressure coefficient as functions of flap deflection, for all model configurations tested, in figures 3 to 19. The resultant tab balance-pressure coefficient is presented for the plain tab only in figure 3(d). The same coefficients are plotted against angle of attack

in figures 20 to 27 (for $\delta_f = 0^\circ$ and $\delta_t = 0^\circ$). Parameter values obtained from these figures are presented in table III. The effects of tab nose shape and tab overhang length on the tab hinge-moment parameters are shown in figures 28 and 29. Figure 30 shows the effect of tab balance on flap section hinge-moment coefficient. The effects of fixing transition and of sealing the tab gap on tab hinge-moment parameters are indicated in figure 31.

Effects of Tab Nose Shape and Overhang

In figure 28 the parameters $c_{ht\alpha}$, $c_{ht\delta_f}$, and $c_{ht\delta_t}$

become more positive as the nose shape is changed from sharp to blunt or as the tab overhang is increased. In general, the parameters are affected by tab balance in the manner that should be expected on the basis of previously obtained test results for the effects of flap balance on flap hinge-moment characteristics (references 4, 7, and 8). Neither tab overhang nor tab nose shape generally has any appreciable effect on the parameters $c_{ht\delta_f}$ or $c_{ht\alpha}$. The tab hinge-moment

effectiveness increases as the tab nose shape is changed from sharp to blunt. Increasing the tab overhang length causes the tab to become more effective with the blunt and round nose shapes but causes irregular results for the tab with the elliptical and sharp nose shapes.

A correlation of the effects of overhang balances for ailerons is expressed (equations (23) and (24) of reference 9) in terms of a factor F_1 related to overhang length and a factor F_2' related to balance nose shape. The relations of these factors to the geometry of the balance are given in reference 9. The correlation has been applied to the tab balances of the present investigation and the results are compared with the experimental values of the parameters $c_{ht\alpha}$ and $c_{ht\delta_t}$. The comparison given in figure 29 shows that

application of the correlation, in its present form, to tabs results in overestimating the effects of the balances on tab hinge moments. The poor agreement between the present experimental results and the correlation probably is caused by the large difference between the tab-chord ratio ($c_t = 0.06c$) of the present tests and the aileron-chord-ratio range ($c_f = 0.155c$ to $0.30c$) used in developing the correlation. Symbols representing different nose shapes for constant overhang lengths and symbols representing different overhang lengths for constant nose shapes fall close, however, to the same line. This agreement indicates that the relative importance of nose shape and overhang length is given accurately by the present correlation. Therefore, the correlation given in reference 9 can possibly be made to

apply to almost any control surface or tab if factors related to the chord ratio were used in addition to the factors F_1 and F_2 .

Figure 30, a plot of flap section hinge-moment coefficient against flap deflection for various ratios of tab deflection to flap deflection shows that the presence of a round-tab balance of 0.50ct length does not greatly alter the effect of the tab on the flap hinge moments. Because a rather extreme tab balance was used for this comparison, tab balance, apparently, is not likely to have any serious adverse effects on flap hinge-moment characteristics for practical installations.

Effects of Transition Strips and Tab Gap

The effects of fixing transition and of sealing the tab gap on hinge-moment parameters are shown in figure 31. Placing transition strips at the 0.01c station causes all the hinge-moment parameters except $c_{ht\alpha}$ to become less negative than they were for the condition of transition strips off; $c_{ht\alpha}$ becomes less positive.

Opening the tab gap causes $c_{hf\alpha}$ and $c_{hf\delta f}$ to become less negative but generally has little effect on $c_{ht\alpha}$, $c_{ht\delta f}$, and $c_{ht\delta t}$. The tab-effectiveness parameter $c_{hf\delta t}$ becomes less negative when the tab gap is unsealed, but the change is much less for a balanced tab than for a plain tab.

Application of Data to Two

Typical Airplanes

In order to illustrate the effects of tab nose shape and tab overhang length on aileron control forces, the hinge-moment data obtained in the present investigation were applied to two typical airplanes having the characteristics listed in table IV. Airplane 1 is a typical fighter-type airplane and airplane 2 is a typical large (transport or heavy bomber) airplane. The ailerons were assumed to be equipped with spring tabs having various spring strengths.

The control force per degree aileron deflection was estimated for each of the tab-nose configurations and for several assumed aileron balances at an assumed indicated airspeed of 300 miles per hour.

The procedure used for estimating the aileron control forces is necessarily approximate since the calculations are based on two-dimensional data. Reliable aspect-ratio corrections for the hinge-moment parameters of partial-span control surfaces or for tabs have not been developed. A qualitative indication of the effects of tab nose shape and tab overhang length on control forces is believed, however, to be obtainable by neglecting all aspect-ratio corrections to the hinge-moment parameters. A correction must be applied to the airfoil section tab-effectiveness parameter $c_{h_f} s_t$, however, when

the tab span is less than the aileron span. The tab correlation given in reference 9 was used to evaluate this correction. On the basis of this assumption, calculations of the control force per degree aileron deflection have been made by means of equation (40) of reference 9. Because of the limitations of the method that have been pointed out, the absolute values of the control force per degree aileron deflection are not considered to be of much significance, but the trends indicated by variation in the tab configuration are believed to be reliable. The hinge-moment parameters of ailerons or tabs with sealed internal balances were calculated by methods described in reference 10 by use of the hinge-moment parameters of plain sealed ailerons and tabs and the resultant balance-pressure parameters. The results of the calculations are presented in figures 32 and 33 as plots of control force per degree aileron deflection against tab overhang length for the nose shapes tested and for several assumed values of aileron balance and spring strength. Figure 32 presents the results obtained for airplane 1 and figure 33 presents the results obtained for airplane 2.

In general, increasing the tab overhang length or the bluntness of the tab nose shape decreases the control force. The results presented in figures 32 and 33 have been summarized in figure 34, which shows the ratio of control force with a balanced tab to control force with a plain tab plotted against spring constant for various values of aileron balance. Figure 34 shows that the effectiveness of the tab balance in reducing control force is practically independent of aileron balance and that the effectiveness decreases as the value of k_3 increases. The greatest percent of reduction occurs for the servotab ($k_3 = 0$).

Calculations were made of the control forces for several assumed sealed internal balances on the tab by using the plain tab data and the tab balance pressures. The results are plotted in figure 35. Control-force curves obtained from figures 32 and 33 for the tabs with round-nose overhangs are included in figure 35 for comparison. In general, the control forces for a sealed internally balanced tab with a plain nose are greater than for a tab with a round nose overhang of the same balance length.

Figure 36 shows the variation of control force per degree aileron deflection with airspeed for various aileron and spring-tab balance conditions and indicates the great reduction in control force possible with balanced spring tabs throughout the speed range.

All of the foregoing control-force results were calculated by the comparatively simple method given in reference 9, which assumes linear variations of aileron and tab hinge-moment coefficients with aileron deflection, spring-tab deflection, and angle of attack. A more difficult, but more accurate, method considering the actual nonlinear aileron and tab curves is given in reference 11. In order to check the validity of the control-force results obtained by the linear method, a plot showing the effect of tab balance on the variation of control force with aileron deflection is presented in figure 37, as determined by references 9 and 11. Although differences in the two sets of results exist, especially at large aileron deflections, figure 37 shows that the trends indicated by the results obtained from the linear method are reliable.

CONCLUSIONS

An investigation was conducted in the $2\frac{1}{2}$ - by 6-foot test section of the Langley stability tunnel of a two-dimensional wing model having a modified NACA 65₁-012 contour with a plain flap having a chord equal to 25 percent of the wing chord and with a tab having several nose shapes and overhang lengths and having a chord equal to 25 percent of the flap chord. The results of the investigation and the application (by an approximate method) of the results to aileron control forces indicated the following conclusions:

1. In general, tab hinge-moment characteristics were affected by tab balance in much the same way that flap hinge-moment characteristics are affected by flap balance.
2. A moderate amount of tab balance would have no adverse effect on flap hinge-moment characteristics.
3. The tab effectiveness decreased when transition strips were placed near the leading edge of the airfoil. Opening the tab gap reduced the tab effectiveness, but the reduction decreased as the tab balance increased.
4. The addition of overhang balance to spring tabs was an effective means of reducing the control forces of spring-tab ailerons.

5.9 Tabs with sealed internal balances were generally less effective in reducing aileron control forces than tabs with round-nose overhangs of the same balance length.

TABLE IV

GEOMETRIC CHARACTERISTICS OF TYPICAL AIRPLANES

	<u>Airplane 1</u>	<u>Airplane 2</u>
Control-stick length or control-wheel radius, r , feet	1.33	0.75
Ratio of control (stick or wheel) deflection to aileron deflection, k_1	1.00	10.00
Ratio of control (stick or wheel) deflection to tab deflection, k_2	-0.333	-3.333
Aileron span, b_a , feet	9.85	24.40
Root-mean-square aileron chord, \bar{c}_a , feet	1.42	4.25
Wing span, b , feet	49.0	130
Wing area, S_w , square foot	400	2816
Tab span, b_t , feet	2.38	8.0
Root-mean-square tab chord, \bar{c}_t , feet	0.354	1.06
Wing aspect ratio, A_w	6.0	6.0
Location of inboard end of aileron, $\frac{y_1}{b/2}$	0.564	0.600
Location of outboard end of aileron, $\frac{y_0}{b/2}$	0.966	0.975
Wing taper ratio, λ	0.25	0.45
Weight, pounds	13,000	80,000
